ABSTRACT

Solid lipid nanoparticles are typically spherical with an average diameter between 1 and 1000 nm. It is an alternative carrier system to tradition colloidal carriers, such as, emulsions, liposomes, and polymeric micro and nanoparticles. Ramipril is an antihypertensive agent used in the treatment of hypertension. Its oral bioavailability is 28% and it is rapidly excreted through the renal route. This drug has many side effects such as, postural hypotension, hyperkalemia, and angioedema, when given as an immediate dosage form. To overcome the side effects and to increase the bioavailability of ramipril, solid lipid nanoparticles of ramipril are prepared by using lipids (glyceryl monostearate and glyceryl monooleate) with stabilizers (tween 80, poloxamer 188, and span 20). The prepared formulations have been evaluated for entrapment efficiency, drug content, *in-vitro* drug release, particle size analysis, scanning electron spectroscopy, Fourier transform-infrared studies, and stability. A formulation containing glyceryl monooleate, stabilized with span 20 as surfactant showed prolonged drug release, smaller particle size, and narrow particle size distribution, as compared to other formulations with different surfactants and lipids.

Key words: Colloidal carriers, ramipril, lipid matrix, surfactants, entrapment efficiency

INTRODUCTION

A drug's therapeutic efficacy depends on four fundamental pathways of drug transport and modification within the body, absorption, distribution, metabolism, and elimination. Failure in therapy includes insufficient drug concentration due to poor absorption, rapid metabolism and elimination, poor drug solubility, and high fluctuation of plasma levels

due to unpredictable bioavailability. A promising strategy to overcome these problems involves the development of a suitable drug colloidal carrier system. Among the colloidal carrier systems solid lipid nanoparticles have many advantages and limited disadvantages as compared to other colloidal carrier systems. Solid lipid nanoparticles (SLN) have gained attention as carriers for the preparation of a wide variety of poorly water soluble drugs due to their biodegradable and biocompatible properties and low toxicity.^[1]

Ramipril, a potent antihypertensive agent has been used in the treatment of hypertensive disorders. It is a highly lipophilic (log *p* octanol/water, 3.32) and poorly water soluble drug, with absolute bioavailability of 28–35%.^[2] It undergoes significant 'first pass' metabolism and the

active metabolite of ramipril is ramiprilate. On the basis of the above fact, the aim of this study is to prepare and characterize the ramipril loaded solid lipid nanoparticles, using glyceryl monostearate and glyceryl monooleate as the lipid matrices and tween 80, poloxamer 188, and span 20, as stabilizers, with a view to improve the dissolution rate of Ramipril, which would increase the biological activities. Given that solid lipid nanoparticles, as an alternative colloidal carrier (transport) system, have the ability to improve the solubility/permeability of lipophilic drugs, they may enhance the drug absorption.^[3]

MATERIALS AND METHODS

Materials

Ramipril and Poloxamer 188 were obtained as a gift sample from Madras Pharmaceuticals, Chennai. Glyceryl monostearate [GMS] (CDH Pvt. Ltd., Mumbai), Glyceryl monooleate [GMO] (Otto Chemicals, Mumbai), Polysorbate 80 (Sisco Research Laboratories, Chennai), Sorbitan monolaurate (Loba Chemie, Mumbai), Chloroform and Methanol (Rankem, Chennai), Dialysis Membrane 50 – LA 387 (Himedia, Mumbai) were purchased from the local market. All the reagents used were of analytical grade.

Preparation of ramipril loaded solid lipid nanoparticles

Ramipril loaded SLN were prepared by hot homogenization followed by the ultrasonication method.^[4] Ramipril and monoglyceride were dissolved in a mixture of methanol and chloroform (1 : 1). Organic solvents were completely removed using a rotary flash evaporator. The embedded lipid layer was melted by heating to 5°C above the melting point of the lipid. An aqueous phase was prepared by dissolving the stabilizers (tween 80 or poloxamer 188 or span 20) in distilled water (sufficient to produce 30 ml) and heating to the same temperature of the oil phase. The hot aqueous phase was added to the oil phase and homogenization was performed (at 2500 rpm and 70°C) using a mechanical stirrer for 30 minutes. The coarse oil in water emulsion so obtained was sonicated using probe soincator for 25 minutes. Ramipril loaded SLN was finally obtained by allowing the hot nanoemulsion to cool to room temperature, and was stored at 4°C in the refrigerator. The composition of the different formulation has been given in Table 1.

In all SLN formulations the lipid concentration was kept constant (as 6% w/v).

Evaluation of ramipril-loaded solid lipid nanoparticles

Entrapment efficiency

The entrapment efficiency of SLN dispersion was determined by the centrifugation method.^[5] SLN dispersion (containing an equivalent to 5 mg of drug) was centrifuged at 20000 rpm for one hour in a refrigerated centrifuge to collect the supernatant liquid. The collected liquid was filtered to measure the free drug concentration after suitable dilution with a fresh phosphate buffer saline pH 7.4. The absorbance was measured at 207 nm in a UV spectrophotometer^[12] to calculate the entrapment efficiency using the following formula:

Entrapment efficiency = Wt. of drug incorporated / Wt. of drug initially taken × 100

In vitro drug release

The *in vitro* release of ramipril from different SLN dispersions was determined using the dialysis bag diffusion technique.^[6] An accurately weighed amount of Ramipril-loaded SLN dispersions containing the drug equivalent to 2.5 mg was transferred to a dialysis bag and sealed. The sealed bag was then suspended in a beaker containing 250 ml of phosphate buffer saline pH 7.4 and stirred at a constant speed of 50 rpm at 37°C ± 0.5°C. Aliquots were withdrawn at predetermined intervals from the receptor compartment up to 12 hours and the same was replaced with fresh buffer. Then the drug content was determined spectrophotometrically by measuring the absorbance at 207 nm using the respective

receptor medium as a blank, to calculate the amount of drug released from the nanoparticles.

Particle size analysis/scanning electron microscopy

The mean diameter of the SLNs in the dispersion was determined by photon correlation spectroscopy (PCS) at a fixed angle of 90°, at 25°C.^[7] Before the measurement, one drop of sample was taken from each selected formulated nanosuspension and diluted in 10 ml of the dispersion medium (distilled water). The surface morphology of SLN was characterized by scanning electron microscopy.^[8]

Fourier transform-infrared studies

The interaction between the lipids and drug was identified from the fourier transform-infrared (FT-IR) studies.^[9]

Stability studies

Stability studies were carried out for the formulations having high entrapment efficiency by storing the formulations at two different temperatures, 4°C and 25 ± 2°C^[10] and the drug content was estimated every 15 days, to find any change in the entrapment efficiency of the SLN.

RESULTS AND DISCUSSION

Entrapment efficiency

Entrapment efficiency is an important parameter for characterizing solid lipid nanoparticles. In order to attain optimal encapsulation efficiency, several factors were varied, including the type and concentration of the lipid and surfactant material used. The entrapment efficiency of all the prepared SLN formulations is shown in Table 1. The entrapment efficiency of the SLN dispersions was found to be in the range of 72.50 to 86.40%.

Effect of surfactants on entrapment efficiency

All SLN formulations prepared with a higher concentration of surfactant (2.0%) showed higher entrapment efficiency [F3 - 81.22%, F6 - 85.70%, F9 - 76.64%, F12 - 77.59%, F15 - 86.40%, and F18 - 82.71%] irrespective of the type of surfactant. This showed that the increase in the concentration of the surfactant increased the entrapment efficiency. This may be due to the increase in the solubility of the drug in the lipid on increasing the concentration of the surfactant. This result was in agreement with the results obtained by Abdelbary *et al.*^[7] Formulations containing span 20 as surfactants showed lower entrapment

efficiency compared to the other surfactants; this could be due to the lower HLB value of Span 20. Hence the entrapment efficiency of various SLNs stabilized with different nonionic surfactants, and decreased in the order of poloxamer 188 > tween 80 > span 20.

In vitro drug release

The *in vitro* drug release profile of ramipril from various SLN formulations is shown in [Figure 1]. The *in vitro* release of ramipril from the SLN dispersion was found to be in the range of 54.90 to 81.40% at the end of 12 hours.

Influence of surfactants on in vitro drug release

Formulations [F3, F6 and F9] prepared by using GMS as a lipid matrix, with Tween 80 2.0%, Poloxamer 188 2.0%, and Span 20 2.0% as stabilizers showed a higher drug release from Ramipril-loaded SLN [79.46, 81.21, and 64.80%, respectively]. This showed that the increase in the concentration of the surfactant there was an increase in the drug release from the SLN. However, this difference could not be attributed to the formulations [F12, F15 and F18] prepared by using GMO as lipid matrix with tween 80 2.0%, poloxamer 188 2.0%, and span 20 2.0%, respectively. These formulations showed a decrease in the drug release on the increase of the concentration of surfactant, which could be due to the lower melting point of the GMO than the GMS. The results indicated that formulation [F6 – GMS + Poloxamer 188 2.0%, (81.40%)] exhibited a higher drug release and formulation [F18 – GMO + Span 20 2.0%, (54.90%)] showed a higher retarded drug release among the three surfactants studied. This could be due to the lower HLB value of Span 20 (8.6) than the other surfactants used as stabilizers. Thus the order of percentage of drug release was Poloxamer 188 > Tween 80 > Span 20 on the basis of the stabilizer.

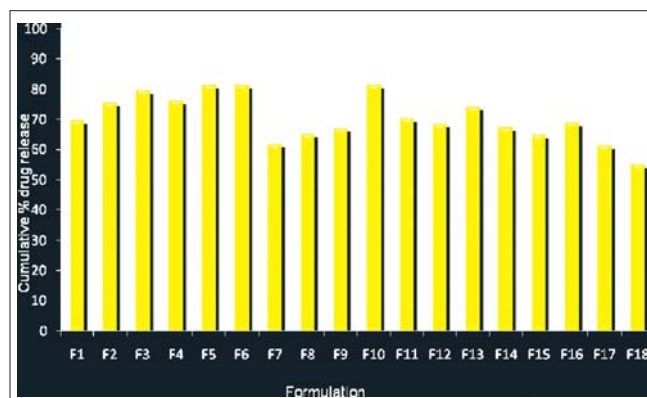

Figure 1: Comparison of *in vitro* drug release profile of ramipril from various solid lipid nanoparticle formulations at the end of 12 hours

Influence of lipids on *in vitro* drug release

Formulations containing GMS as a lipid matrix exhibited higher drug release than the formulations containing GMO as the lipid matrix, which showed a more sustained release. GMO produced less ordered crystals than GMS, leading to lower drug expulsion from the imperfect lattice, contributing to the prolonged release of the lipophilic drug. Moreover, GMO was a lipid with a lower melting point when compared to GMS. Zur Muhlen *et al.*,^[11] reported that a lower melting point could produce a controlled release from SLN. The order of percentage of drug release was Glyceryl monostearate > Glyceryl monooleate on the basis of the lipid matrix. Thus, it could be well concluded that the amount of drug released was much slower and controlled from the SLN dispersions prepared by using GMO as the lipid matrix, with Span 20 as the surfactant, than that from the ramipril-pure drug solution [Figure 2].

Particle size analysis

Figure 3 shows the effect of the lipid and surfactant concentration on the particle size distribution of ramipril-loaded SLN prepared by using GMS and GMO with poloxamer 188 2.0%, tween 80 2.0%, and span 20 2.0%. The particle size ranged from 104 nm – 334 nm. There was a significant difference in the size of the particles, with change in the lipids.

Effect of lipids on the particle size of ramipril SLN

Ramipril-loaded solid lipid nanoparticles, prepared by using GMS as the lipid matrix, resulted in larger particle size compared to SLN prepared by using GMO as the lipid matrix, with all type of surfactants studied. This phenomenon could be attributed to the melting point of the lipid, GMS has a higher melting point than GMO, which results in a slower lipid crystallization from the hot homogenized condition resulting in an increase in the particle size. The particle size of various SLNs prepared with different lipids was in the order of GMS > GMO.

Effect of surfactants on the particle size of ramipril SLN

SLN dispersion prepared using poloxamer 188 2.0% as stabilizer [F6 and F15] showed lower particle size than the other surfactants irrespective of the lipids studied. This result could be explained due to the higher molecular weight of poloxamer 188 and higher HLB value of poloxamer 188 when compared to tween 80 and span 20.^[12] The particle size of various SLN, stabilized with different surfactants,

increased in the order of Poloxamer 188 > Tween 80 > Span 20.

Scanning electron microscopy

SEM studies showed that the ramipril-loaded solid lipid nanoparticles had a spherical shape with a smooth surface as shown in Figure 4.

FT-IR studies

Infrared studies were carried out to confirm the compatibility between the lipid, drug, and selected SLN formulation. From the spectra it was observed that there was no major shifting, as well as, no loss of functional peaks between the spectra of

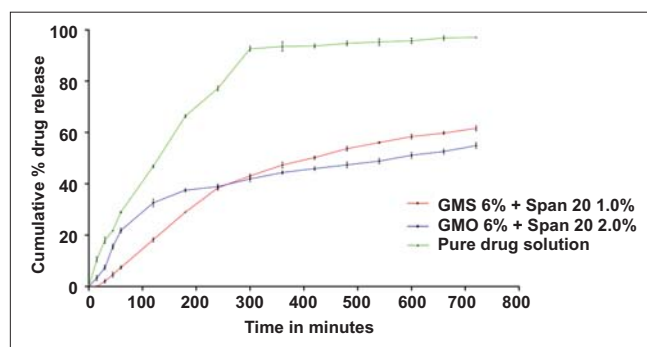

Figure 2: Comparison of *in vitro* drug release of SLN prepared by using GMS 6%, GMO 6% and pure drug solution

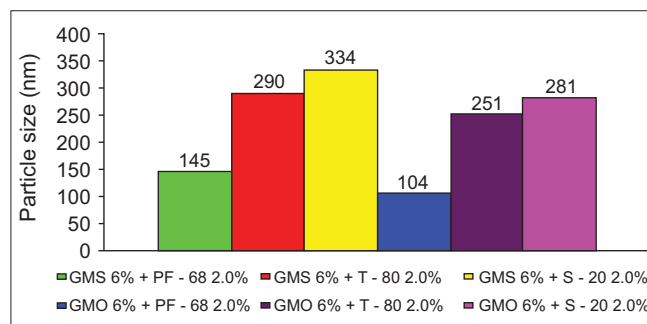

Figure 3: Comparison of particle size of SLN of GMS 6% and GMO 6% (PF – 68 2.0%, T – 80 2.0%, and S – 20 2.0%)

Figure 4: F15 – GMO 6% + Poloxamer 188 2.0%

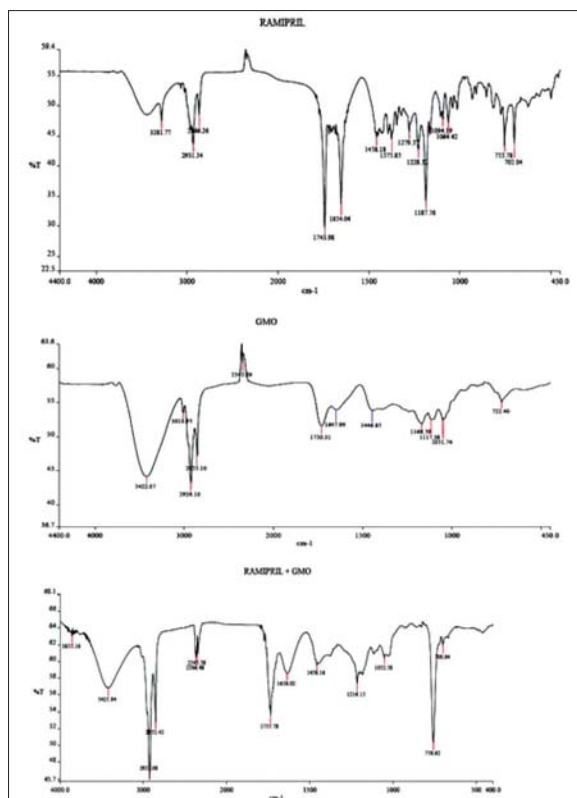

Figure 5: Comparison of I.R spectrum of pure drug, GMO and pure drug + GMO

the drug, lipid, and drug-loaded SLN. [1743.98 cm^{-1} , 4654.04 cm^{-1} , 1458.18 cm^{-1} , and 2931.34 cm^{-1}]. This indicated no interaction between the drug and lipid [Figure 5].

Stability studies

The results showed that the entrapment efficiency of the SLN dispersion stored in 4°C was more compared to the SLN dispersion stored in 25°C \pm 2°C. This may be due to more drug expulsion from the lipid matrices at higher temperature [Table 2].

CONCLUSION

It was observed that the hot homogenization and ultrasound dispersion method was a useful method for the successful incorporation of the poor water-soluble drug ramipril with high entrapment efficiency. Furthermore, it could be presumed that if the nanometer range particles were obtained, the bioavailability might be increased. Hence, we can conclude that solid lipid nanoparticles provide controlled release of the drug

Table 2: Stability studies for solid lipid nanoparticles (Percentage of entrapment efficiency at refrigerated temperature and 25° \pm 2°C)

Formulation	Immediately after preparation (%)	15 th day (%)		30 th day (%)	
		4°C	25° \pm 2°C	4°C	25° \pm 2°C
F3	81.22	81.06	78.16	80.00	75.31

F18	82.71	82.15	81.86	81.57	77.69

and these systems are used as drug carriers for lipophilic drugs, to enhance the bioavailability of poorly water-soluble drugs through nanoparticles, as a drug delivery system.
